HiPEAC

=

High-Performance and Embedded Architecture and Compilation

HiPEAC's mission is to steer and increase the European research in the area of high-performance and embedded computing systems,

and stimulate cooperation between

a) academia and industry and

b) computer architects and tool builders.

Thirteenth International Summer School on Advanced Computer Architecture and Compilation for High-Performance and Embedded Systems

9-15 July 2017, Fiuggi, Italy

Computer performance has increased by over 1,000-fold in the past three decades. This astonishing growth has fuelled major innovations across all aspects of society. New advances in drug discovery and diagnosis, product design and manufacturing, transportation and energy, scientific and environmental modelling, social networking and entertainment, financial analysis, all depend on continued increases in computer system performance. Computing systems are so fundamental to today's society that they represent a basic resource, and form a strategic foundation for many of our most powerful and versatile tools and developments. Maintaining rapid growth in computing performance is key for tackling the societal challenges shaping Europe and assuring our global competitiveness in the future.

**Early registration deadline
March 31 2017**

Slot 1

Moinuddin Qureshi
Advanced Topics in
Memory Systems

Gernot Heiser
Operating systems for
secure and safe embedded
systems

Giacomo Indiveri
Neuromorphic Electronic
Circuits for Compact Low-
Power Real-Time Neural
Processing Systems

Slot 2

Michael Hübner
Reconfigurable Hardware,
Tools and Applications

Rosa Badia
Application programming
on parallel/distributed
computing platforms

**Koen Bertels and Carmen G.
Almudever**
Quantum computing: from
circuit to architecture

Slot 3

Tushar Krishna
High-Performance On-Chip
Interconnects for
Emerging SoCs

Mike Ferdman

A single-board computer made in Europe

Cyber-physical systems meet supercomputing

In April, we saw another indicator of the booming popularity of the DIY electronics scene, when the Kickstarter campaign for the UD00 X86 board smashed its €100,000 target overnight. Thanks to the EU-funded AXIOM (www.axiom-project.eu) and Mont-Blanc (www.montblanc-project.eu) projects, a new and improved version of Barcelona Supercomputing Center's Omp5s parallel programming model can be run on a cluster of UD00 X86, allowing hobbyists and professionals to craft their own supercomputer. The AXIOM team aims to create a single-board computer – a complete computer comprising microprocessor(s), memory, input/output and other features on one circuit board – which is designed and manufactured in Europe.

HiPEAC caught up with UD00 co-founder Maurizio Caporali (MC) of the University of Siena and Xavier Martorell (XM) of Barcelona Supercomputing Center to find out more.

UD00 X86 has the same pinout as an Arduino 101 and is 100% compatible with Arduino shields, sensors and actuators. It can even run the Arduino integrated development environment directly from the main Intel quad core processor. The Arduino 101-compatible microcontroller is based on Intel Curie, which integrates 32-bit Quark SE system-on-chip, six-axis motion sensors and Bluetooth low energy. Last but not least, UD00 X86 is open source and open hardware.

UD00 X86: Vital statistics

- Processor up to 2.56GHz
- Up to 8GB of RAM
- Drives up to three 4K monitors simultaneously
- Completely Arduino 101-integrated
- Runs any X86 Linux distribution, Windows and Android
- Multiple options for mass storage
- Ability to start up processor through on-board microcontroller

Why are do-it-yourself (DIY) electronics so popular? What are the benefits of making things open source?

MC: Hardware is becoming less expensive year by year, and people have started realizing that they can build their own stuff instead of buying it. Recently there's also been more focus on STEAM (science, technology, engineering, arts and mathematics) fields. What we are witnessing is not just a bunch of hobbyists; it's a new industrial revolution, embodied by makers.

What's so special about this new board?

MC: UD00 X86 is a unique single-board computer. It's both the world's most powerful maker board and a fully fledged Arduino 101. As a computer, UD00 X86 is a quantum leap forward compared to regular single-board computers for makers, and its performance is comparable to most notebooks. It can drive up to three 4K screens – that is, screens with a horizontal resolution of around 4,000 pixels – simultaneously and run Windows (including Windows 10), Android and Linux. It is 10 times more powerful than the Raspberry Pi 3. Despite this incredible power, its Intel Quad Core 14nm 64-bit processors consume as little as 5-6W in energy, depending on the UD00 X86 model.

But there's an... it's a natural... have program... for those sam... program the v...

Video processing algorithms to boost edge and motion detection

August 08, 2016 // By Julien Happich

0 Comments

Researchers at the Czech Institute of Information Theory and Automation (UTIA) have demonstrated video processing algorithms for the Sundance EMC2 platform using the Xilinx system-on-chip (SDSoC) 2015.4 design environment.

Hardware accelerators used in the demonstration were found to achieve up to eight times faster edge detection and 50 times faster motion detection without a significant increase in power dissipation, hence significantly reducing energy consumption.

Three edge detection and three motion detection video processing designs were demonstrated on the Sundance EMC2 platform. The results for image processing will enhance embedded applications in security, medical imaging and unmanned vehicles.

Silexica reach German Entrepreneur Award finals

SILEXICA

Congratulations to Silexica, the RWTH Aachen University spin-off specializing in multicore software design automation, on being named one of three finalists for the German Entrepreneur Award 2017 in the Startup category. At the time of going to press the winners had not been announced.

In April, the company released the latest version (2017.4) of its SLX Tool Suite. This release provides many new features to improve the efficiency of multicore programming and code distribution. These include:

- The SLX Parallelizer now has a powerful reconfigurable cache analyser that simulates cache behaviour and estimates usage statistics.

- The SLX Mapper has a new set of visualization capabilities providing deeper insights into application runtime behaviour of computed/simulated mappings.
- The SLX Generator now features added support for additional processor cores such as 32-bit ARMv7 and 64-bit ARMv8, as well as Linux-based Power-PC 32-bit and 64-bit processors.
- The SLX Automotive Development package is now available with the rest of the SLX tools.

European Commission dangles €374m for low-power exascale research

Processors are going to be everywhere, so they should be energy hogs

14 Nov 2016 at 07:28, Richard Chirgwin

Europe is trying to plant a flag in future chip development, slinging money toward low-power server silicon.

Policy Corner

The 2017 call for proposals is coming

The next call for proposals "ICT-05-2017: Customised and low energy computing" will open in December, with a new topic on processor hardware which will be of interest to the HIPEAC community.

A few words of introduction: the overall strategy of the European Commission is to support jobs, growth and investments through digital technologies. European companies are strong in industrial markets like avionics, health and automotive, and the relevant objective of the Horizon2020 Research and Innovation Programme is to develop the technologies that will be used in these sectors in the coming years.

One of the main problems in these sectors is the need for a radical change in the way software is developed, especially because it is still difficult to design efficient programs for recent system architectures (heterogeneous, highly parallel). For this reason, the first version of the 2016-2017 Work Programme was based on software ("Programming paradigms and toolboxes for low power and highly parallel computing"). In 2016, the Commission has seen a stronger policy focus on technologies for digitizing industry, and it was possible to allocate extra funding for hardware research: the EC will now fund projects in the range of €6-10 million to start the development of next-generation high-performance processors.

Towards the "exascale" performance of tomorrow's fastest supercomputers, but it also means to support all the applications where high performance must be coupled with low energy consumption, and criteria like efficiency and space are relevant; in general, these are the requirements of many cyber-physical systems and of many applications requiring computing power also at the edge of the network.

The Work Programme does not impose specific technical solutions: the only strict requirements are to improve significantly the energy/performance ratio compared to the state of the art, and to develop a design that can be manufactured in volume at a reasonable cost. We do not just want a computer design exercise, but something that will change the market in the coming years.

For this reason, the call text asks for a "working prototype". Developing and

manufacturing an actual silicon chip is extremely expensive and the timescales are not compatible with those of an EU-funded project, so we do not specify what the prototype should be (actual chip, software simulator, hybrid hardware-software demonstrator or anything else): the important point is that the prototype should convince hardware experts that the objectives of the project have been achieved.

Here lies the challenge: the EU needs you to develop the computer chips of tomorrow. These are the chips which will drive your car, make your city's subway faster, monitor your health and maybe even foresee the exact time and location of the next earthquake before it strikes. If you are reading these lines in the HIPEAC info newsletter, you are part of the community that can do it.
